

Extensible Neural Networks with Backprop

Justin Le

This write-up is a follow-up to the *MNIST* tutorial (rendered¹ here, and literate haskell² here). This write-up itself is available as a literate haskell file³, and also rendered as a pdf⁴.

The (extra) packages involved are:

- hmatrix
- lens
- mnist-idx
- mwc-random
- one-liner-instances
- singletons
- split

Introduction

The *backprop*⁵ library lets us manipulate our values in a natural way. We write the function to compute our result, and the library then automatically finds the *gradient* of that function, which we can use for gradient descent.

In the last post, we looked at using a fixed-structure neural network. However, in this blog series⁶, I discuss a system of extensible neural networks that can be chained and composed.

One issue, however, in naively translating the implementations, is that we normally run the network by pattern matching on each layer. However, we cannot directly pattern match on BVars.

We *could* get around it by being smart with prisms and `^?`, to extract a “Maybe BVar”. However, we can do better! This is because the *shape* of a Net `i` `hs` `o` is known already at compile-time, so there is no need for runtime checks like prisms and `^?`.

Instead, we can just directly use lenses, since we know *exactly* what constructor will be present! We can use singletons to determine which constructor is present, and so always just directly use lenses without any runtime nondeterminism.

Types

First, our types:

```

data Layer i o =
  Layer { _lWeights :: !(L o i)
        , _lBiases  :: !(R o)
        }
deriving (Show, Generic)

```

⁵<http://hackage.haskell.org/package/backprop>

⁶<https://blog.jle.im/entries/series/+practical-dependent-types-in-haskell.html>

```

instance NFData (Layer i o)
makeLenses ''Layer

data Net :: Nat -> [Nat] -> Nat -> Type where
  NO   :: !(Layer i o) -> Net i [] o
  (:~) :: !(Layer i h) -> !(Net h hs o) -> Net i (h ': hs) o

```

Unfortunately, we can't automatically generate lenses for GADTs, so we have to make them by hand.⁷

```

_NO :: Lens (Net i [] o) (Net i' [] o')
             (Layer i o) (Layer i' o' )
_NO f (NO l) = NO <$> f l

 NIL :: Lens (Net i (h ': hs) o) (Net i' (h ': hs) o)
             (Layer i h) (Layer i' h)
 NIL f (l :~ n) = (:~ n) <$> f l

 NIN :: Lens (Net i (h ': hs) o) (Net i (h ': hs') o')
             (Net h hs o) (Net h hs' o')
 NIN f (l :~ n) = (l :~) <$> f n

```

You can read `_NO` as:

```
_NO :: Lens' (Net i [] o) (Layer i o)
```

A lens into a single-layer network, and

```

 NIL :: Lens' (Net i (h ': hs) o) (Layer i h)
 NIN :: Lens' (Net i (h ': hs) o) (Net h hs o)

```

Lenses into a multiple-layer network, getting the first layer and the tail of the network.

If we pattern match on `Sing hs`, we can always determine exactly which lenses we can use, and so never fumble around with prisms or nondeterminism.

Running the network

Here's the meat of process, then: specifying how to run the network. We re-use our `BVar`-based combinators defined in the last write-up:

```

runLayer
  :: (KnownNat i, KnownNat o, Reifies s W)
  => BVar s (Layer i o)
  -> BVar s (R i)
  -> BVar s (R o)
runLayer l x = (l `^` 1Weights) #>! x + (l `^` 1Biases)
{-# INLINE runLayer #-}

```

For `runNetwork`, we pattern match on `hs` using singletons, so we always know exactly what type of network we have:

```

runNetwork
  :: (KnownNat i, KnownNat o, Reifies s W)
  => BVar s (Net i hs o)
  -> Sing hs

```

⁷We write them originally as a polymorphic lens family to help us with type safety via parametric polymorphism.

```

-> BVar s (R i)
-> BVar s (R o)
runNetwork n = \case
  SNil           -> softMax . runLayer (n ^^. _NO)
  SCons SNat hs -> runNetwork (withSingI hs (n ^^. _NIN)) hs
    . logistic
    . runLayer (n ^^. _NIL)
{# INLINE runNetwork #-}

```

The rest of it is the same as before.

```

netErr
  :: (KnownNat i, KnownNat o, SingI hs, Reifies s W)
  => R i
  -> R o
  -> BVar s (Net i hs o)
  -> BVar s Double
netErr x targ n = crossEntropy targ (runNetwork n sing (constVar x))
{# INLINE netErr #-}

trainStep
  :: forall i hs o. (KnownNat i, KnownNat o, SingI hs)
  => Double          -- ^ learning rate
  -> R i              -- ^ input
  -> R o              -- ^ target
  -> Net i hs o       -- ^ initial network
  -> Net i hs o
trainStep r !x !targ !n = n - realToFrac r * gradBP (netErr x targ) n
{# INLINE trainStep #-}

trainList
  :: (KnownNat i, SingI hs, KnownNat o)
  => Double          -- ^ learning rate
  -> [(R i, R o)]   -- ^ input and target pairs
  -> Net i hs o       -- ^ initial network
  -> Net i hs o
trainList r = flip $ foldl' (\n (x,y) -> trainStep r x y n)
{# INLINE trainList #-}

testNet
  :: forall i hs o. (KnownNat i, KnownNat o, SingI hs)
  => [(R i, R o)]
  -> Net i hs o
  -> Double
testNet xs n = sum (map (uncurry test) xs) / fromIntegral (length xs)
  where
    test :: R i -> R o -> Double          -- test if the max index is correct
    test x (extract->t)
      | HM.findIndex t == HM.findIndex (extract r) = 1
      | otherwise                                = 0
    where
      r :: R o
      r = evalBP (\n' -> runNetwork n' sing (constVar x)) n

```

And that's it!

Running

Everything here is the same as before, except now we can dynamically pick the network size. Here we pick '[300, 100]' for the hidden layer sizes.

```
main :: IO ()
main = MWC.withSystemRandom $ \g -> do
    Just train <- loadMNIST "data/train-images-idx3-ubyte" "data/train-labels-idx1-ubyte"
    Just test <- loadMNIST "data/t10k-images-idx3-ubyte" "data/t10k-labels-idx1-ubyte"
    putStrLn "Loaded data."
    net0 <- MWC.uniformR @Net 784 '[300,100] 10) (-0.5, 0.5) g
    flip evalStateT net0 . forM_ [1..] $ \e -> do
        train' <- liftIO . fmap V.toList $ MWC.uniformShuffle (V.fromList train) g
        liftIO $ printf "[Epoch %d]\n" (e :: Int)

    form_ ([1..] `zip` chunksOf batch train') $ \(b, chnk) -> StateT $ \n0 -> do
        printf "(Batch %d)\n" (b :: Int)

        t0 <- getCurrentTime
        n' <- evaluate . force $ trainList rate chnk n0
        t1 <- getCurrentTime
        printf "Trained on %d points in %.s.\n" batch (show (t1 `diffUTCTime` t0))

        let trainScore = testNet chnk n'
            testScore = testNet test n'
        printf "Training error: %.2f%%\n" ((1 - trainScore) * 100)
        printf "Validation error: %.2f%%\n" ((1 - testScore) * 100)

    return ((), n')
where
    rate = 0.02
    batch = 5000
```

Looking Forward

One common thing people might do is want to be able to mix different types of layers. This could also be easily encoded as different constructors in `Layer`, and so `runLayer` will now be different depending on what constructor is present.

In this case, we can either:

1. Have a different indexed type for layers, so that we can always know exactly what layer is involved, so we don't have to runtime pattern match:

```
data LayerType = FullyConnected | Convolutional

data Layer :: LayerType -> Nat -> Nat -> Type where
    LayerFC :: .... -> Layer 'FullyConnected i o
    LayerC :: .... -> Layer 'Convolutional i o
```

We would then have `runLayer` take `Sing (t :: LayerType)`, so we can again use `^~.` and directly pattern match.

2. Use a typeclass-based approach, so users can add their own layer types. In this situation, layer types

would all be different types, and running them would be a typeclass method that would give our `BVar s (Layer i o) -> BVar s (R i) -> BVar s (R o)` operation as a typeclass method.

```
class Layer (l :: Nat -> Nat -> Type) where
    runLayer
        :: forall s. Reifies s W
        => BVar s (l i o)
        -> BVar s (R i)
        -> BVar s (R o)
```

In all cases, it shouldn't be much more cognitive overhead to use `backprop` to build your neural network framework!

And, remember that `evalBP` (directly running the function) introduces virtually zero overhead, so if you only provided `BVar` functions, you could easily get the original non-`BVar` functions with `evalBP` without any loss.

What now?

Ready to start? Check out the docs for the `Numeric.Backprop`⁸ module for the full technical specs, and find more examples and updates at the [github repo](#)⁹!

Internals

That's it for the post! Now for the internal plumbing :)

```
loadMNIST
    :: FilePath
    -> FilePath
    -> IO (Maybe [(R 784, R 10)])
loadMNIST fpI fpL = runMaybeT $ do
    i <- MaybeT           $ decodeIDXFile      fpI
    l <- MaybeT           $ decodeIDXLabelsFile fpL
    d <- MaybeT . return $ labeledIntData l i
    r <- MaybeT . return $ for d (bitraverse mkImage mkLabel . swap)
        liftIO . evaluate $ force r
    where
        mkImage :: VU.Vector Int -> Maybe (R 784)
        mkImage = create . VG.convert . VG.map (\i -> fromIntegral i / 255)
        mkLabel :: Int -> Maybe (R 10)
        mkLabel n = create $ HM.build 10 (\i -> if round i == n then 1 else 0)
```

HMatrix Operations

```
infixr 8 #>!
